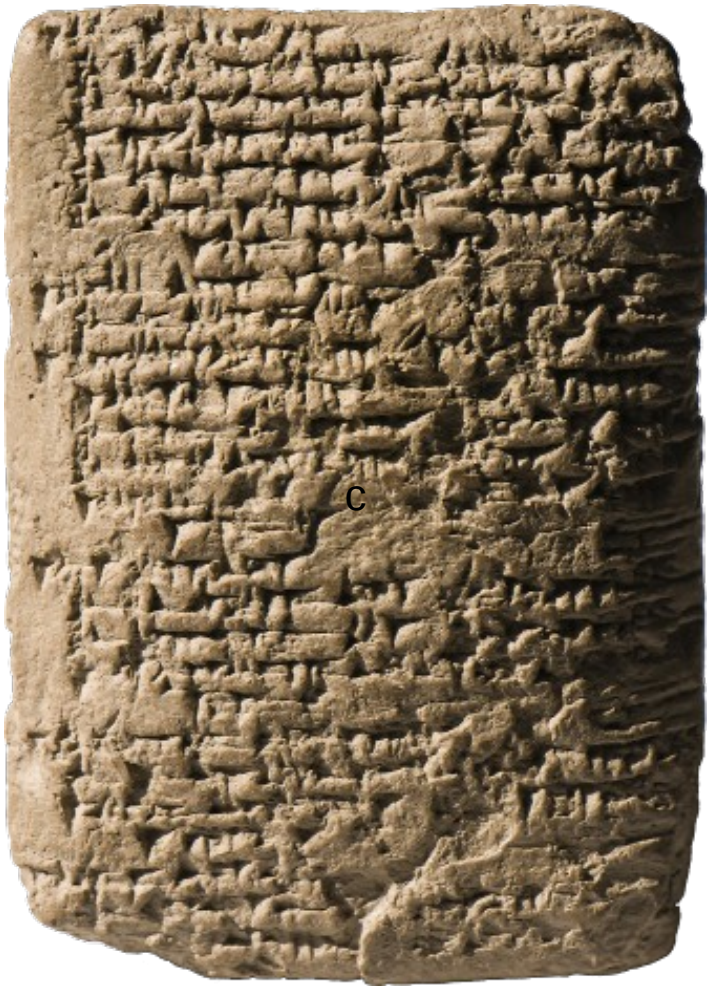
Cuneiform Script

- More than 3,000 years of history
- Evolved from a pictographic to a syllabic script
- More than 500,000 clay tablets
- Only few Assyriologists



Cuneiform Script

- Cuneiform is a writing system used by at least 7 different languages
- Written by impressing a rectangular stylus in wet clay
- Our approach models geometric patterns instead of language

Goal

- Only few tablets are transliterated
- Transliterations can be incomplete and subjective
- Provide a mechanism for searching by graphical query

Born-digital

Unification of sources requires a common geometrical representation

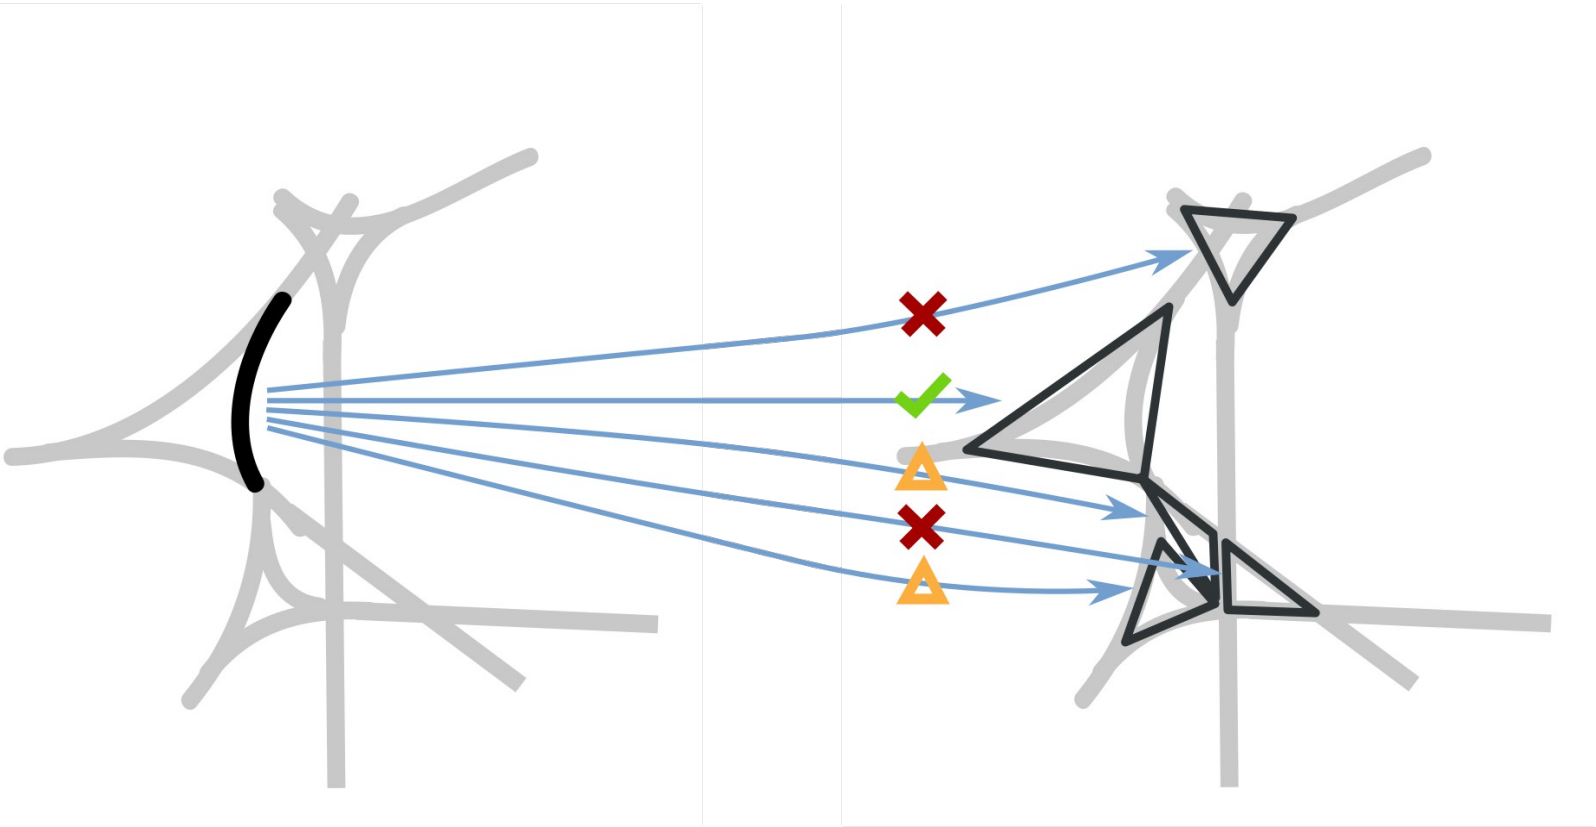
Extracting Wedges

- We model wedges as triangles with arms
- Find possible candidate wedges by finding cycles
- Prune this set of candidates using modeling constraints
  - No overlapping wedges
  - Sizes and angles are within sane bounds
  - Prioritize bigger wedges

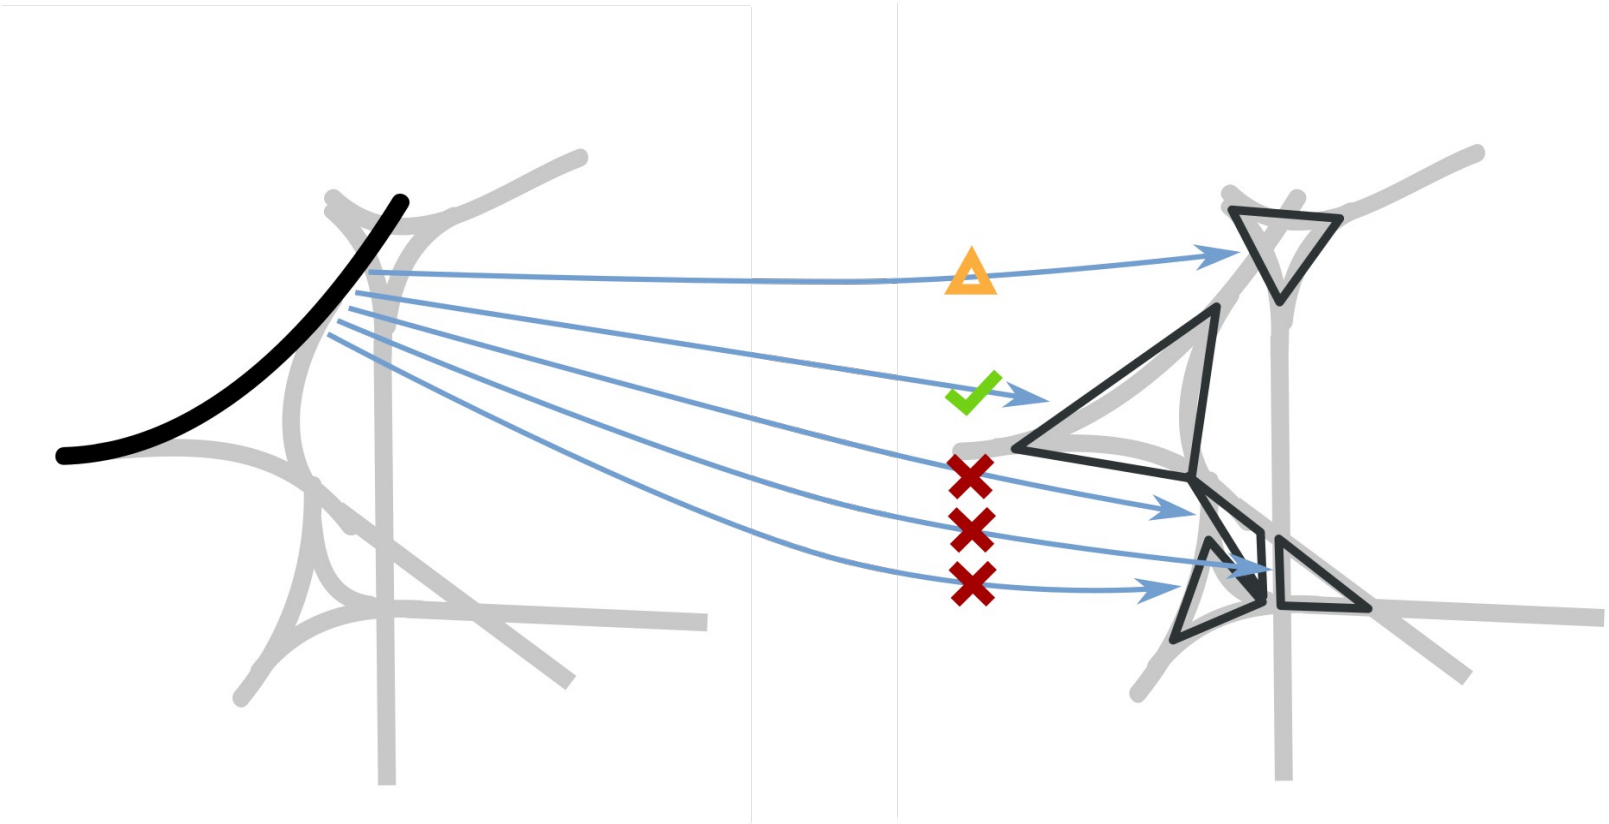
Extracting Wedges

- We re-formulate this constraint satisfaction task as an optimizing assignment task
- This enables us an efficient *O(n^3)* solution
- The set of strokes is being assigned to a set of candidate wedges

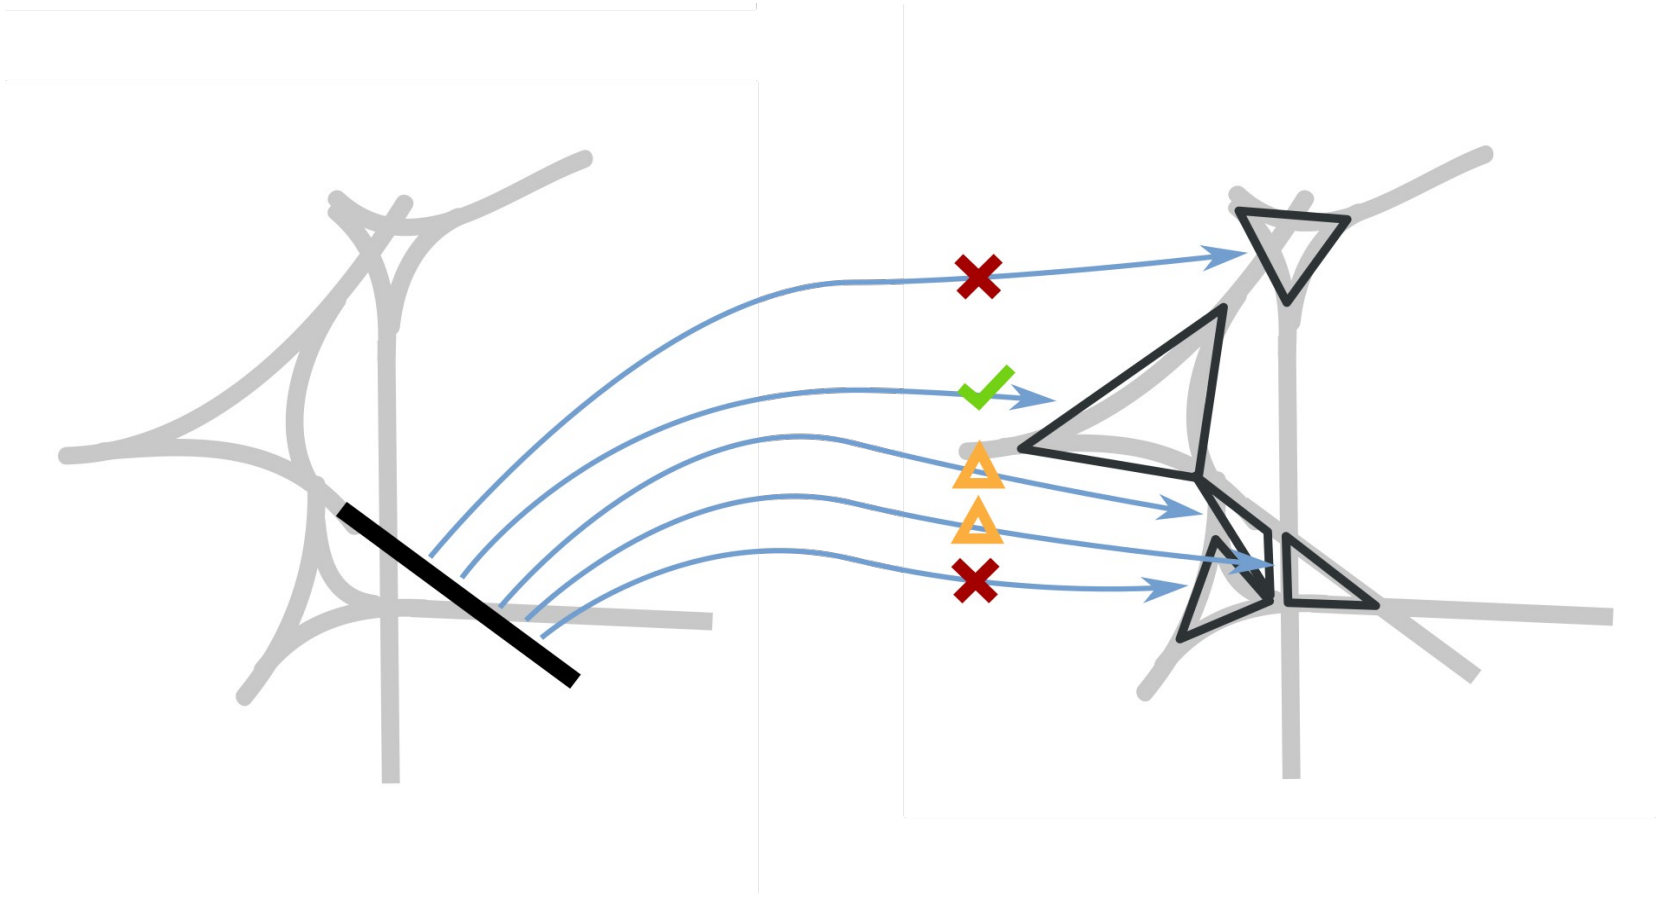
Optimal Assignment



Optimal Assignment



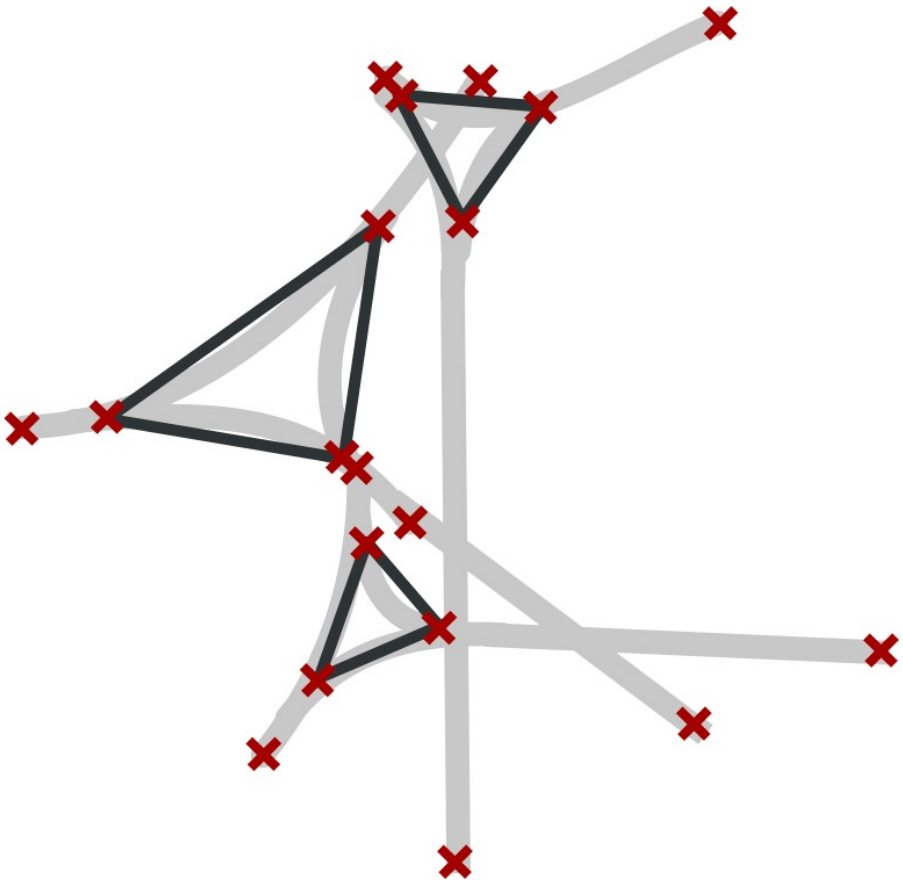
Optimal Assignment



Optimal Assignment

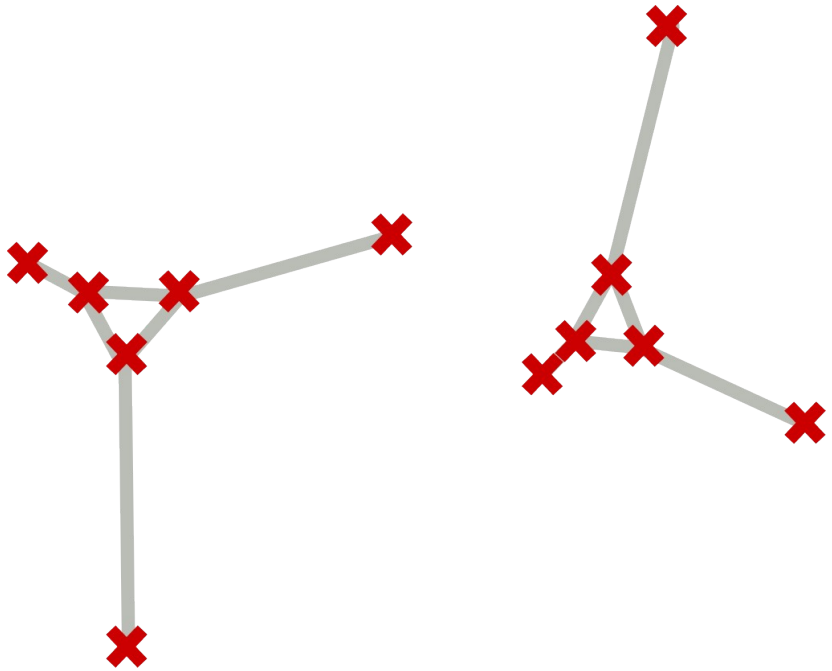
Wedge Features

- We want to represent extracted wedges as feature vectors
- Intersections and endpoints are most salient points in wedges
- Model wedges using these keypoints



Keypoint Model

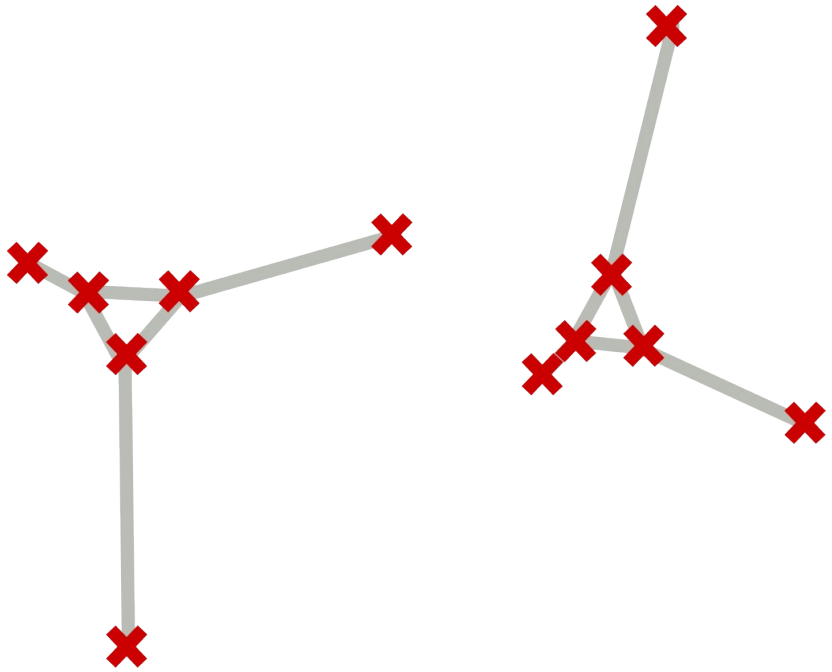
- Feature vector is a concatenation of the keypoints in our wedge model
  - Wedge-head intersections
  - Wedge-arm endpoints



$$f^k = (\overbrace{x_1y_1\ x_2y_2\ x_3y_3}^{\text{Wedge-head}}\ \overbrace{x_4y_4\ x_5y_5\ x_6y_6}^{\text{Wedge-arms}})$$

Keypoint Model

- Features are compared by Euclidean distance

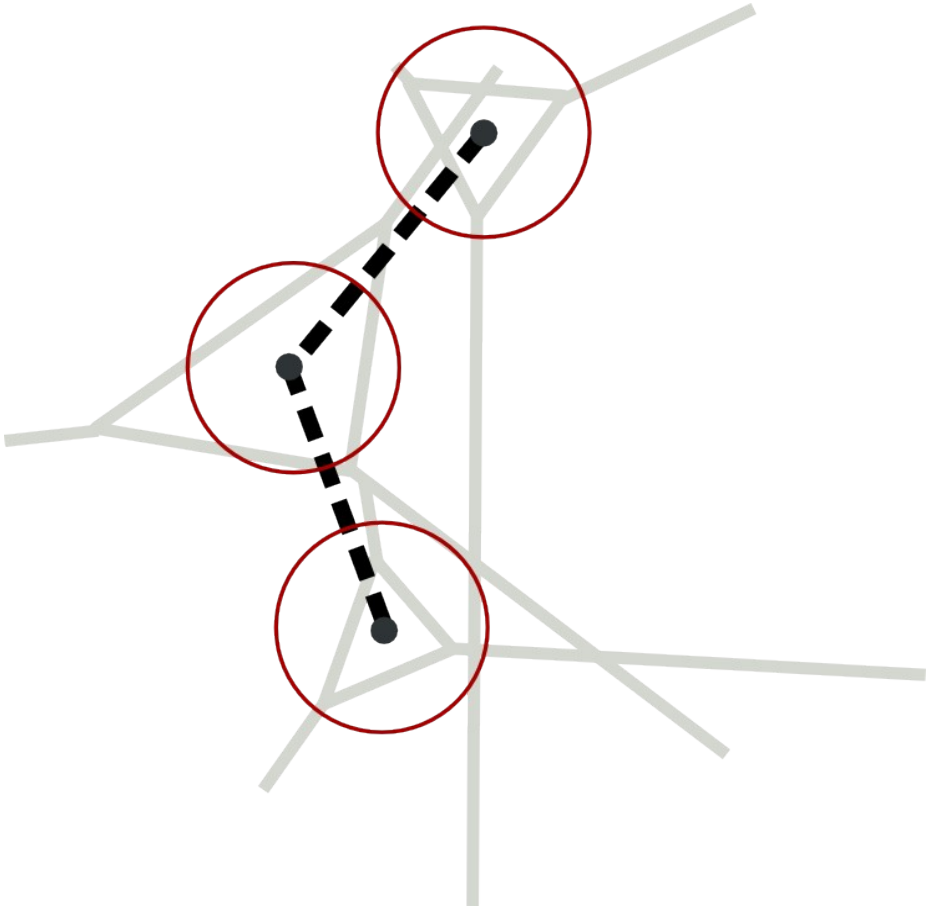


- Our new approach reorders points using optimal assignment

$$f^k = (\overbrace{x_1 y_1 \; x_2 y_2 \; x_3 y_3}^{\text{Wedge-head}} \; \overbrace{x_4 y_4 \; x_5 y_5 \; x_6 y_6}^{\text{Wedge-arms}})$$

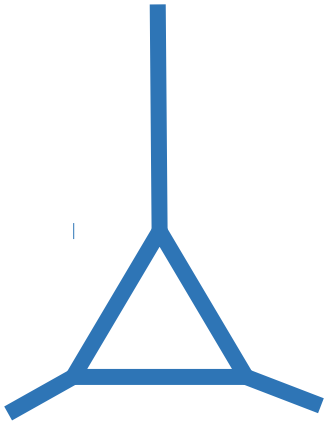
Part-structured Spotting

- Model characters as wedges connected by tree of flexible links
- Align query to candidates by deforming links
- Probability of a match is wedge similarities plus amount of link deformation

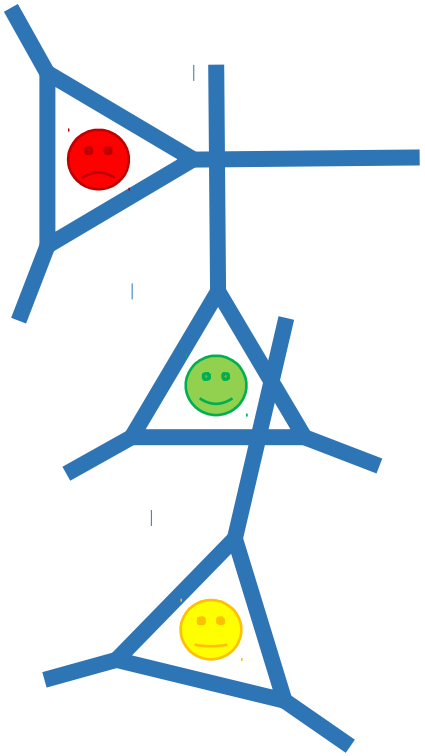


Generalized Distance Transform

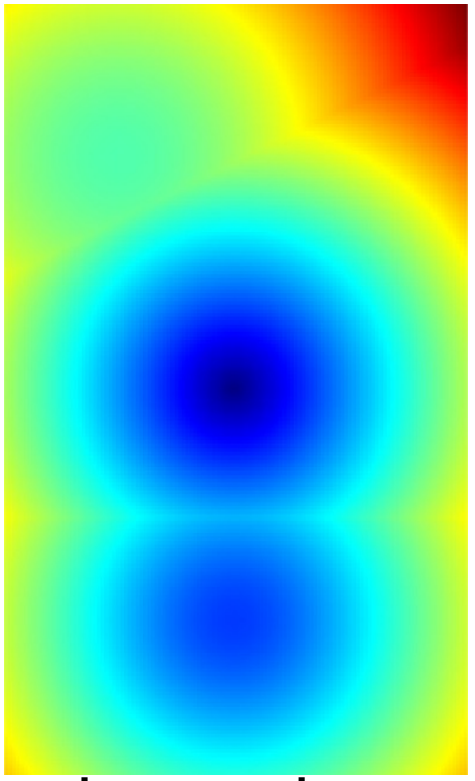
Query



Target



GDT



- Trades off between wedge similarity and distance

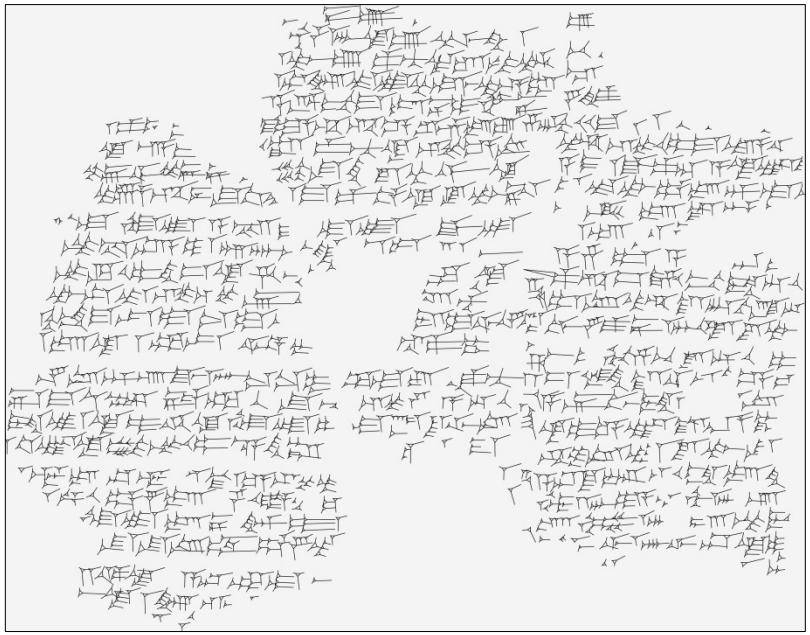
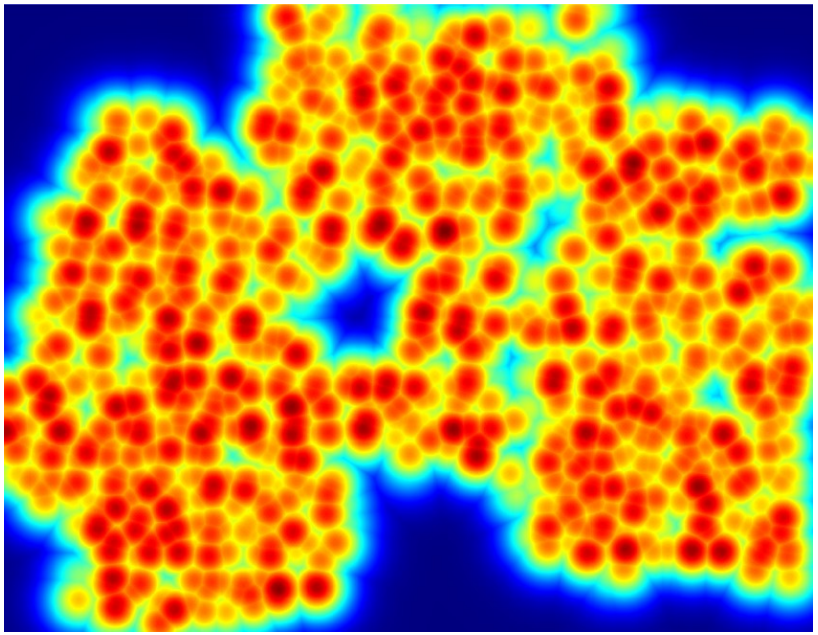
Sample Results





Evaluation

- Symbol spotting task with 40 query symbols of various lengths

- We compare against Rothacker et al. HMM Latin word spotting
  - No elevation data to evaluate their approach for cuneiform spotting
  - We rasterize our data to make it available for their method

Evaluation

- Dataset are two cuneiform tablets with 500 identifiable characters
- Tablets are only incompletely labeled, precluding an automated evaluation
- Retrieval results are checked by an expert for false positives

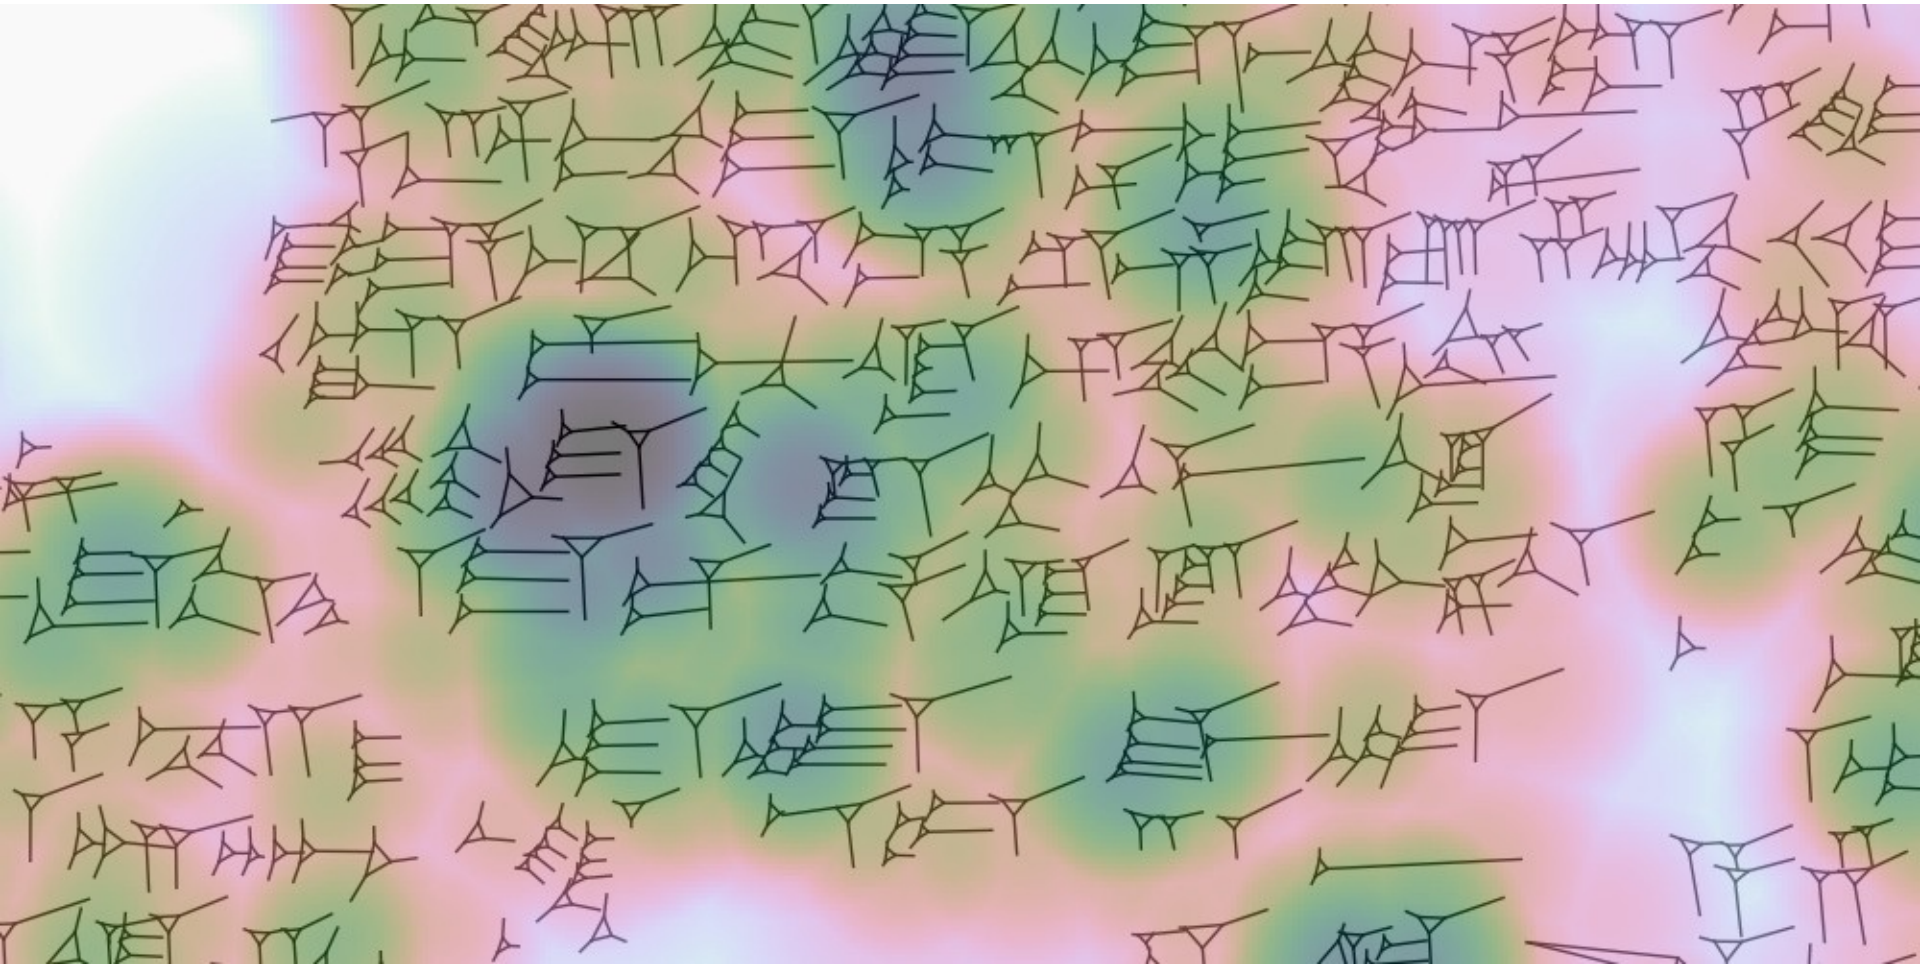
Query Results



Summary

- Fast and optimizing method for cuneiform wedge detection
- Native and accurate feature representation of cuneiform wedges
- Fast symbol spotting of cuneiform characters
